Computational Methods in Engineering

Introduction to Optimization

Outline

• Introduction
• The Merit Function
• Rectangle Algorithm
Introduction

What is Optimization?

Optimization is simply finding the minimum or a maximum of a function. In this regard, it is similar to root finding.

The function is usually chosen to be a measure of how “good” something is.

Merit function
Fitness function
Quality function
Cost Function
...

Maximum occurs at (2,1)

Iteration 77 (2.00, 1.00)
A Simple Example

Suppose we need to choose $f$ and $d$ so as to prevent diffraction into the zero-order transmitted mode for a normally incident wave.

What values of $f$ and $d$ do this?

Global Best Vs. Local Best

The solution space is often sprinkled among many possible solutions (local extrema). It is the primary goal of optimization to find the absolute best solution (global extremum). Without having some apriori knowledge of the solution, however, it is usually impossible to determine if the solution is a global best solution.
Common Optimization Algorithms

• Direct Methods
  • Complete Search
  • Gradient Methods

• Stochastic Optimization
  • Particle Swarm Optimization
  • Genetic Algorithms
  • Simulated Annealing

Notes on Optimization

• Stochastic methods are used most effectively when very little is known about the solution space. That is, when the engineer has no idea what the best design will look like.

• Unless something is known about the solution space, it is not possible to certify that the global best solution has been found. As engineers, we are usually satisfied with “good enough” solutions.

• Only an exhaustive complete search can guarantee a global best solution has been found.

• Direct methods converge very fast, but can only find local best solutions.

• It’s much more about the merit function instead of the algorithm.
We need a single number that tells us how “good” a particular solution is. This is called the merit function. The optimization can attempt to minimize or maximize this merit function. In this case, our merit function is the diffraction efficiency in the zero-order transmitted mode and we want to minimize it.

\[ M(f, d) = T_0 \equiv \text{transmittance of zero-order mode} \]

Global minimum:
\[ f = 0.49 \]
\[ d = 0.28 \]
Rethink the Merit Function!!

In the previous case, the global best was a very narrow region. This probably isn’t feasible when fabrication tolerances are considered. It also assumes the model is perfectly accurate. It is often good practice to include some type of “bandwidth” in your merit function to pick a minimum that is also broad and robust.

\[
M(f, d) = \frac{T_0}{W_0} \quad W_0 \equiv \text{width of extrema}
\]

Transmittance of the zero-order mode

![Transmittance graph]

Revised global minimum
\[
f = 0.32 \\
d = 0.75
\]

Multiple Considerations

The merit function can be challenging to formulate when multiple things must be considered.

There is no cookbook way of doing this. It is up to the ingenuity of the engineer to arrive at this.

A common approach is to form a product where each term is a separate consideration.

\[
M = \frac{A_1 \cdot A_2 \cdot A_3 \cdots A_M}{B_1 \cdot B_2 \cdot B_3 \cdots B_N}
\]

Parameters we wish to maximize (minimize)
Parameters we wish to minimize (maximize)
Incorporating Relative Importance

If the considerations are not of equal importance, we need a way to enhance or suppress their impact on the merit function.

We usually cannot just scale them by a constant.

\[ M = aA_1 \cdot bA_2 \cdot cA_3 = abc(A_1 \cdot A_2 \cdot A_3) \]

There are some other effective ways of doing this.

\[ M = A_1^\alpha \cdot A_2^\beta \cdot A_3^\gamma \] exponents
\[ M = A_1 \cdot \log(A_2) \cdot A_3 \] logarithms
\[ M = A_1 \cdot (1 + A_2) \cdot A_3 \] adding constants
\[ M = A_1^\alpha \cdot (1 + A_2)^\beta \cdot \log(1 + A_3) \] hybrids

Example (1 of 2)

Suppose we wish to optimize the design of an antenna.

We are probably most concerned about its bandwidth \( B \) and efficiency \( E \). Based on this, we could define a merit function as

\[ M = B \cdot E \]

Are these equally important?

The Shannon capacity theorem sets a limit on the bit rate \( C \) of data given the bandwidth \( B \) of the channel and the signal-to-noise ratio \( \text{SNR} \).

\[ C = B \log_2 (1 + \text{SNR}) \]

This shows that bandwidth and efficiency are not equally important.
Example (2 of 2)

We can come up with a better merit function that is inspired by the Shannon capacity theorem.

\[ M = B \log_2 (1 + E) \]

Maybe size \( L \) is also a consideration. We want data rate as high as possible using an antenna as small as possible. A new merit function that considers size could be

\[ M = \frac{B}{L} \log_2 (1 + E) \quad \text{This merit function, however, would approach infinity as } L \text{ approaches zero, leading to a false solution.} \]

This problem can be fixed by adding a constant to \( L \).

\[ M = \frac{B}{1 + L} \log_2 (1 + E) \]

Rectangle Algorithm
Goal of the Algorithm

Suppose we wish to design a broadband reflector. We construct an initial design and simulate the reflectance. Using a single quantity, what is the performance of this preliminary design?

A Very Common Merit Function

In electromagnetics, we are most often interested in maximizing performance (i.e. reflectance here) over some bandwidth.

\[ MF = (\text{Bandwidth}) \times (\text{Performance}) \]
The Rectangle Algorithm

We can calculate the merit function by finding the biggest rectangle that fits under a curve. But...which rectangle is biggest?

Steps in the Rectangle Algorithm

• Step 0 – Decide on a merit function.
• Step 1 – Simulate the spectrum of the device.
• Step 2 – Loop over all points in spectra.
  • i. Seek left to place left edge of rectangle.
  • ii. Seek right to place right edge of rectangle.
  • iii. Calculate merit function.
• Step 3 – Overall merit function is the area of the largest rectangle found in Step 2.
Animation of Rectangle Construction

Animation of the Rectangle Algorithm (1 of 3)

$MF = w \cdot h$
Animation of the Rectangle Algorithm (2 of 3)

$$MF = \log(1 + w) \cdot h^3$$

Animation of the Rectangle Algorithm (3 of 3)

$$MF = w^3 \cdot \log(1 + h)$$
An Example Merit Function

Suppose you want to minimize transmission through a device where your application requires it to be broadband. You need both minimum transmission and wide bandwidth.

\[ M \sim |T| \cdot \text{BW} \]
